## Lab 2 – Functions and Pointers

**Lab session** – One hour is scheduled for the lab session. There are 3 questions in this lab.

**Note:** You do not need to submit your code for this lab.

**Lab Questions 1-3**

You may use the program template in Figure 1 to test your functions in the following three questions. The program contains a **main**() which includes a switch statement so that the following functions can be tested by the user.  Write the code for each function and use the suggested test cases to test your code for correctness.

```c
#include <stdio.h>
/* function prototypes */
int numDigits1(int num);
int digitPos1(int num, int digit);
int square1(int num);
void numDigits2(int num, int *result);
void digitPos2(int num, int digit, int *result);
void square2(int num, int *result);

int main()
{
  int choice;
  int number, digit, result=0;
  do {
    printf("\nPerform the following functions ITERATIVELY:\n");
    printf("1:  numDigits1()\n");
    printf("2:  numDigits2()\n");
    printf("3:  digitPos1()\n");
    printf("4:  digitPos2()\n");
    printf("5:  square1()\n");
    printf("6:  square2()\n");
    printf("7:  quit\n");
    printf("Enter your choice: ");
    scanf("%d", &choice);

    switch (choice) {
      case 1:
        printf("Enter the number: \n");
        scanf("%d", &number);
        printf("numDigits1(): %d\n", numDigits1(number));
        break;
      case 2:
        printf("Enter the number: \n");
        scanf("%d", &number);
        numDigits2(number, &result);
        printf("numDigits2(): %d\n", result);
        break;
      case 3:
```

```c
      printf("Enter the number: \n");
      scanf("%d", &number);
      printf("Enter the digit: \n");
      scanf("%d", &digit);
      printf("digitPos1(): %d\n", digitPos1(number, digit));
      break;
    case 4:
      printf("Enter the number: \n");
      scanf("%d", &number);
      printf("Enter the digit: \n");
      scanf("%d", &digit);
      digitPos2(number, digit, &result);
      printf("digitPos2(): %d\n", result);
      break;
    case 5:
      printf("Enter the number: \n");
      scanf("%d", &number);
      printf("square1(): %d\n", square1(number));
      break;
    case 6:
      printf("Enter the number: \n");
      scanf("%d", &number);
      square2(number, &result);
      printf("square2(): %d\n", result);
      break;
    default: printf("Program terminating .....\n");
      break;
    }
  } while (choice < 7);
  return 0;
}
/* add function code here */
int numDigits1(int num)
{
  int count = 0;
  do {
    count++;
    num = num/10;
  } while (num > 0);
  return count;
}
void numDigits2(int num, int *result)
{
  *result=0;
  /* Write your code here */
}
int digitPos1(int num, int digit)
{
  /* Write your code here */
}
void digitPos2(int num, int digit, int *result)
```

```
{
   int pos=0;
    *result=0;
    do {
      pos++;
      if (num%10 == digit){
        *result = pos;
         break;
      }
      num = num/10;
   } while (num > 0);
}
int square1(int num)
{
   /* Write your code here */
}
void square2(int num, int *result)
{
   /* Write your code here */
}
```

<p style="text-align:center">Figure 1</p>

1. **(numDigits)** Write a function that counts the number of digits for a non-negative integer. For example, 1234 has 4 digits. The function **numDigits1()** returns the result. The function prototype is given below:

   int numDigits1(int num);

   Write another function **numDigits2()** that passes the result through the pointer parameter, *result*. The function prototype is given below:

   void numDigits2(int num, int *result);

   For separate program testing: The following sample program template is given for testing the functions:

```
#include <stdio.h>
int numDigits1(int num);
void numDigits2(int num, int *result);
int main()
{
   int number, result=0;
   printf("Enter the number: \n");
   scanf("%d", &number);
   printf("numDigits1(): %d\n", numDigits1(number));
   numDigits2(number, &result);
   printf("numDigits2(): %d\n", result);
   return 0;
}
int numDigits1(int num)
```

```c
{
     int count = 0;
     do {
       count++;
       num = num/10;
     } while (num > 0);
     return count;
}
void numDigits2(int num, int *result)
{

  /* Write your code here */
}
```

Some sample input and output sessions are given below:

(1)  Test Case 1:
Enter the number:
1
numDigits1(): 1
numDigits2(): 1

(2)  Test Case 2:
Enter the number:
13579
numDigits1(): 5
numDigits2(): 5

```c
#include <stdio.h>
int numdigits1(int num);
void numdigits2(int num,int *result);
int main()
{
   int number,result=0;
   printf("Enter the number: \n");
   scanf("%d",&number);
   printf("numdigits1():%d\n",numdigits1(number));
   numdigits2(number,&result);
   printf("numdigits2():%d\n",result);
   return 0;
}
int numdigits1(int num)
{
   int count = 0;
   do
   {
       count++;
       num = num/10;
   }
   while(num>0);
   return count;
}
void numdigits2(int num,int *result)
{
   *result = 0;
   *result = numdigits1(num);
}
```

2.  **(digitPos)** Write the function **digitPos1()** that returns the position of the first appearance of a specified digit in a positive number. The position of the digit is counted from the right and starts from 1. If the required digit is not in the number, the function should return 0. For example, digitPos1(12315, 1) returns 2 and digitPos1(12, 3) returns 0. The function prototype is given below:

```c
int digitPos1(int num, int digit);
```

Write another function **digitPos2()** that passes the result through the pointer parameter, *result*. For example, if num = 12315 and digit = 1, then *result = 2 and if num=12 and digit = 3, then *result = 0. The function prototype is given below:

```c
void digitPos2(int num, int digit, int *result);
```

For separate program testing: The following sample program template is given for testing the functions:

```c
#include <stdio.h>
int digitPos1(int num, int digit);
void digitPos2(int num, int digit, int *result);
int main()
{
   int number, digit, result=0;
   printf("Enter the number: \n");
```

```c
    scanf("%d", &number);
    printf("Enter the digit: \n");
    scanf("%d", &digit);
    printf("digitPos1(): %d\n", digitPos1(number, digit));
    digitPos2(number, digit, &result);
    printf("digitPos2(): %d\n", result);
    return 0;
}
int digitPos1(int num, int digit)
{
    /* Write your code here */
}
void digitPos2(int num, int digit, int *result)
{
    int pos=0;
    *result=0;
    do {
        pos++;
        if (num%10 == digit){
            *result = pos;
            break;
        }
        num = num/10;
    } while (num > 0);

}
```

Some sample input and output sessions are given below:

(1) Test Case 1:
Enter the number:
234567
Enter the digit:
6
digitPos1(): 2
digitPos2(): 2

(2) Test Case 2:
Enter the number:
234567
Enter the digit:
8
digitPos1(): 0
digitPos2(): 0

```c
#include <stdio.h>
int digitpos1(int num, int digit);
void digitpos2(int num, int digit, int *result);
int main()
{
    int number,digit,result=0;
    printf("Enter the number: \n");
    scanf("%d",&number);
    printf("Enter the digit:\n");
    scanf("%d",&digit);
    printf("digitpos1():%d\n",digitpos1(number,digit));
    digitpos2(number,digit,&result);
    printf("digitpos2():%d\n",result);
    return 0;
}
int digitpos1(int num,int digit)
{
    int pos = 0;
    do{
        pos++;
        if(num%10 == digit)
        {
            return pos;
        }else
        {
            num = num/10;
        }
    }while(num>0);
}
void digitpos2(int num, int digit, int *result)
{
    int pos = 0;
    *result = 0;
    do{
        pos++;
        if(num%10 == digit){
            *result = pos;
            break;
        }
        num = num/10;
    }while(num>0);
}
```

3. **(square)** Write a function **square1()** that returns the square of a positive integer number *num*, by computing the sum of odd integers starting with 1 as shown in the example below. The result is returned to the calling function. For example, if *num* = 4, then $4^2 = 1 + 3 + 5 + 7 = 16$ is returned; if *num* = 5, then $5^2 = 1 + 3 + 5 + 7 + 9 = 25$ is returned. The function prototype is:

```c
int square1(int num);
```

Write another function **square2()** that passes the result through the pointer parameter, *result*. For example, if *num* = 4, then $*result = 4^2 = 1 + 3 + 5 + 7 = 16$; if *num* = 5, then $*result = 5^2 = 1 + 3 + 5 + 7 + 9 = 25$. The function prototype is:

```c
void square2(int num, int *result);
```

For separate program testing: The following sample program template is given for testing the functions:

```c
#include <stdio.h>
int square1(int num);
void square2(int num, int *result);
int main()
{
  int number, result=0;
  printf("Enter the number: \n");
  scanf("%d", &number);
  printf("square1(): %d\n", square1(number));
  square2(number, &result);
  printf("square2(): %d\n", result);
  return 0;
}
int square1(int num)
{
  /* Write your code here */
}
void square2(int num, int *result)
{
  /* Write your code here */
}
```

Some sample input and output sessions are given below:

(1) Test Case 1:
Enter the number:
4
square1(): 16
square2(): 16

(2) Test Case 2:
Enter the number:
0
square1(): 0
square2(): 0

```c
#include <stdio.h>
int square1(int num);
void square2(int num, int *result);
int main()
{
   int number,result=0;
   printf("Enter the number: \n");
   scanf("%d",&number);
   printf("square1():%d\n",square1
(number));
   square2(number,&result);
   printf("square2():%d\n",result);
   return 0;
}
int square1(int num)
{
   return num*num;
}
void square2(int num, int *result)
{
   *result = square1(num);
}
```

```c
int square1(int num)
{
   int count=0, k=1,result=0;
   while(count<num)
   {
     result+=k;
     k+=2;
     count++;
   }
   return result;
}
```

```c
void square(int num, int *result)
{
  int count=0, k=1;
  *result=0;
  while(count<num)
  {
     *result +=k;
     k+=2;
     count++;
  }
}
```
